Abstract

Adrenal myelolipomas (AMLs) are unusual non-functioning benign tumours composed of adipose and hematopoietic tissues. It is usually diagnosed accidentally and nowadays much more frequently because of widespread use of ultrasonography, computed tomography (CT) and magnetic resonance imaging. Adrenal myelolipoma is usually unilateral and asymptomatic, though known to be associated with obesity, hypertension, endocrinological disorders and some malignancies. We present a 48 years-old female patient, obese with no medical history and a painless right-sided mass. CT scan suggested the diagnosis of giant adrenal myelolipoma. The complete preoperative laboratory exams showed a non-functioning tumour. The patient underwent open right adrenalectomy and the pathological study confirmed the diagnosis of adrenal myelolipoma. AMLs discovered incidentally and CT scan remains the gold standard of diagnosis. The open surgery approach is the suggested treatment for giant AMLs (>10cm) while the laparoscopic and robotic surgery has been used in only a few cases.

Key words:

Giant, asymptomatic, adrenal, myelolipoma, incidentaloma

Clinical Image

Adrenal myelolipomas (AMLs) are unusual non-functioning benign tumours composed of adipose and hematopoietic tissues. It is usually diagnosed accidentally and nowadays much more frequently because of widespread use of ultrasonography, computed tomography (CT) and magnetic resonance imaging. Adrenal myelolipoma is usually unilateral and asymptomatic, though known to be associated with obesity, hypertension, endocrinological disorders and some malignancies. We present a 48 years-old female patient, obese with no medical history and a painless right-sided mass. CT scan suggested the diagnosis of giant adrenal myelolipoma (Fig 1). The complete preoperative laboratory exams showed

a non-functioning tumour. The patient underwent open right adrenalectomy (Fig. 2) and the pathological study confirmed the diagnosis of adrenal myelolipoma. AMLs discovered incidentally and CT scan remains the gold standard of diagnosis. The open surgery approach is the suggested treatment for giant AMLs (>10cm) while the laparoscopic and robotic surgery has been used in only a few cases.

Figure 1

A,B: Axial CT image shows a giant heterogeneous fat tumor – adrenal incidentaloma, with pressure atrophy of the right liver's lobe and hypertrophy of the left one.

C,D: Axial MRI scan shows a giant fat tumor – adrenal incidentaloma with highlighted (T1 weighted image) and suppressed fat (T2 weighted image).

Figure 1. Abdomen CT scan shows a giant

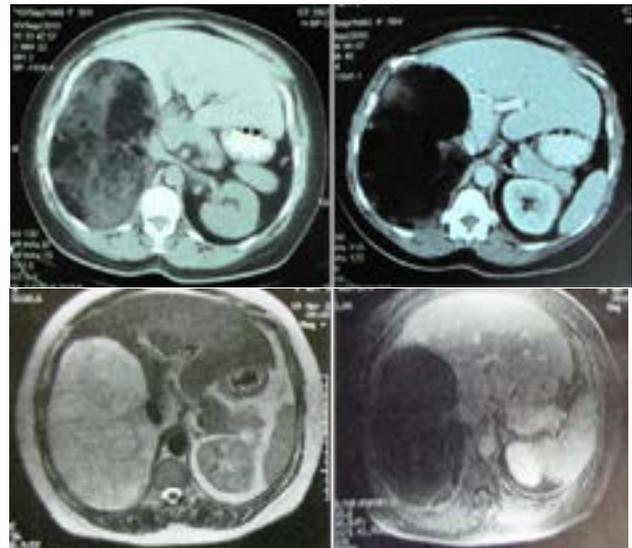

Figure 2

A,B: Giant adrenal incidentaloma – myelolipoma (28x15x8cm, 1585gr). Frontside and backside of the surgical specimen. The capsule was intact and resolved during surgery. C,D: Cross section of the surgical specimen shows fat (yellow) and adipose (red) tissue.
